ABSTRACT

Simple sum procedure of the conditional PDF approach (plausiblity of distractor function) combined with the normal approach method was applied for estimating the plausibility functions of the distractors of the Level II vocabulary subtest items of the Iowa Tests of Basic Skills. In so doing, the normal ogive model was adopted for the correct answers of those items, and those items were used as the substitute for the old test. The subjects were 2,364 fourth to ninth grade students who took the Level II tests. Results indicated the existence of informative distractors for certain test items, and it was confirmed that most items fit the informative distractor model (stating that the incorrect chosen distractor does provide information) rather than the equivalent distractor model. The model validation study indicated that, for most items, the normal ogive model was suitable for their correct answers. (Extensive graphs and data tables are included). (Author/GDC)

PLAUSIBILITY FUNCTIONS OF IOWA VOCABULARY TEST ITEMS ESTIMATED BY THE SIMPLE SUM PROCEDURE OF THE CONDITIONAL P.D.F. APPROACH

ABSTRACT

Simple Sum Procedure of the Conditional P.D.F. Approach combined with the Normal Approach Method was applied for estimating the plausibility functions of the distractors of the Level 11 Vocabulary Subtest items of the Iowa Tests of Basic Skills. In so doing, the normal ogive model was adopted for the correct answers of those items, and those items were used as the substitute for the Old Test. The group of subjects consists of 2,364 students who took the Level 11 tests in 1971 through 1977. The results indicate the existence of informative distractors for certain test items, and it is confirmed that most items belong to the Informative Distractor Model rather than the Equivalent Distractor Model. The model validation study accompanied to it indicates that for most items the normal ogive model is suitable for their correct answers.

The research was conducted at the principal investigator's laboratory, 405 Austin Peay Hall, Department of Psychology, University of Tennessee, Knoxville, Tennessee. Those who worked for her as assistants include Paul S. Changas, Vicki R. Newton, Mehrdad A. Saravi, Deborah Wichlan and Cindy Wheatley-Lovoy.

I. Introduction

Three-parameter logistic model (Birnbaum, 1968) has been popular among researchers who deal with multiple-choice test items. The model is based upon the knowledge or random guessing principle, which assumes that the examinee either knows the answer or guesses randomly. In that model, each item is scored either right or wrong, depending upon whether the examinee has chosen the correct answer or one of the incorrect alternative answers. It should be noted that following the three-parameter model each incorrect alternative answer is treated as equivalent to each other, and it is implicitly assumed that, owing to the subjects' random guessing behavior, those distractors have identical operating characteristics. We will not lose any information, therefore, even if we recategorize all the incorrect alternative answers into a single category, and assign zero as the item score to those who have chosen any one of the distractors. Such a family of models belongs to the Equivalent Distractor Model.

Samejima has proposed a new family of models for the multiple-choice test item (Samejima, RR-79-4), which assumes that the examinee chooses one of the distractors for his answer more or less intentionally, and, therefore, each incorrect alternative answer, as well as the correct answer, provides us with its unique information. In those models, the examinee's random guessing behavior is still taken into consideration, but only as the last resource when he has no idea as to which alternative is more plausible as the answer to the question. The plausibility function of each distractor, which is the

conditional probability assigned to the choice of that particular distractor, given ability, is the information source. If a model in the family fits our multiple-choice test data, then we shall be able to estimate the examinee's ability more accurately, using information obtained from the distractors as well as from the correct answers. Thus the multiple-choice test item is no longer a "blurred image" of the free-response test item, but it has a unique status as a test item which provides us with information that the free-response test item is not able to. Such a family of models belongs to the Informative Distractor Model.

It will be worthwhile to estimate the plausibility functions of the distractors of existing test items, to find out if, indeed, each distractor provides us with its unique information. In so doing we need some nonparametric method of estimating the operating characteristics, for we have no idea what type of mathematical function each plausibility function follows. Molding it into some parametric form from the very beginning will be harmful, therefore, more than helpful.

In the present study, a subset of the data collected on the Iowa Tests of Basic Skills was used as "existing data". It is based upon the Vocabulary Test items for Level 11. The whole set of data was obtained with the courtesy of Professor William Coffman of the University of Iowa, and was introduced in a previous research project (Samejima and Trestman, RR-80-1). For brevity, hereafter, we shall call the whole set Iowa Test Data. Its brief description will be

given in Section 2.

In estimating the plausibility function of each distractor of each test item, Simple Sum Procedure of the Conditional P.D.F. Approach combined with the Normal Approach Method was used (cf. Samejima, Final Report, 1981). A brief description of the Simple Sum Procedure of the Conditional P.D.F. Approach and the Normal Approach Method will be given in Section 3, in comparison with other methods and approaches developed by the author.

II. Iowa Test Data

Iowa Test Data are based upon the Iowa Tests of Basic Skills, Form 6, Levels 9-14 (Hieronymus and Lindquist, 1971). These tests have been designed, constructed and revised at the College of Education of the University of Iowa since 1935, with the general school population in mind. Each of the level numbers, 9 through 14, corresponds to the age of subjects who are suitable for the subset of test items that specific level contains. Thus the tests are designed basically for the fourth through ninth graders.

There are eleven tests in the battery, each of which focuses upon a different basic skill. The numbers of test items in the eleven separate tests vary within the range of 74 through 178, including all the six levels. Table 2-1 presents these eleven tests, the numbers of test items and some other information related to their administration.

The data were collected in three different school systems in

TABLE 2-1

Iowa Tests of Basic Skills, Form 6, Numbers of Items, Administration Sessions and Time Limits.

Test	Number of Items	Administration Session	Working Time (Minutes)
V: Vocabulary	114	First Session	17

Total	82	133	82	73	73	53	67	48	99	90	61	861

the State of Iowa, in the years 1971 through 1977, using the subtests of Levels 11, 12 and 13. Table 2-2 presents the number of test items contained by each of the three levels, for each of the eleven tests. Since there are overlapping test items between two, or even three, adjacent levels, the total number of items in each test is less than the sum of the numbers of items in the three separate subtests.

In the original data, there are 2,460 examinees who took the subtests of Level 11, 2,452 who took those of Level 12, and 2,527 who took those of Level 13, to make the total number of examinees 7,439. With close examination of those original data, however, certain examinees who omitted too many test items were excluded, and the resulting "revised data" are based upon 7,246 examinees in total, with 2,364, 2,413 and 2,469 for those who took the three separate levels of subtests, respectively (cf. Samejima and Trestman, RR-80-1).

In the present study, the results of the 2,364 examinees on the Level 11 Vocabulary Subtest were analyzed. The choice of Level 11 was more or less arbitrary, but the Vocabulary Subtest was selected more intentionally, due to the factor analysis result which will be introduced in Section 5. This subtest has forty-three test items, each of which has four alternative answers, i.e., one correct answer plus three distractors.

III. Simple Sum Procedure of the Conditional P.D.F. Approach and Normal Approach Method

Samejima's methods and approaches of estimating the operating characteristics of discrete item responses were introduced in previous

research reports (Samejima, RR-77-1, RR-78-1, RR-78-2, RR-78-3, RR-78-4, RR-78-5, RR-78-6), and were summarized later (Samejima, Final Report, 1981). They are characterized by two features, i.e.,

1) estimation is made without assuming any mathematical forms for the operating characteristics of discrete item responses, and

2) estimation is efficient enough to base itself upon a relatively small set of data of, say, several hundred to a few thousand examinees.

There are two main approaches, one of which is called Bivariate P.D.F. Approach, and the other is called Conditional P.D.F. Approach. In the former approach, we approximate the bivariate distribution of the transformed latent trait τ and its maximum likelihood estimate $\hat{\tau}$, for each of the subgroups of examinees who share the same discrete item response to a specified item. Thus the procedure must be repeated as many times as the number of discrete item response categories for each item. In contrast to this, in the Conditional P.D.F. Approach, this is done for the total group of subjects. Effort is focused upon the approximation of the conditional distribution of τ, given $\hat{\tau}$, for the total group of examinees, and then the result is branched into separate discrete item response subgroups for each item. This latter approach is further categorized into three procedures, i.e., Simple Sum Procedure, Weighted Sum Procedure and Proportioned Sum Procedure. In each approach, there are three methods of approximating the conditional distribution of τ, given $\hat{\tau}$, and they are called Pearson System Method, Two-Parameter

Beta Method and Normal Approach Method, respectively.

It is appropriate to say that, theoretically, Bivariate P.D.F. Approach is a more orthodox approach, and Conditional P.D.F. Approach is a simplified version of the former. The latter approach has two big advantages, however, in the sense that the CPU time required is substantially less, and that it does not have to deal with subgroups of small numbers of subjects in approximating the joint bivariate distributions of τ and $\hat{\tau}$. It is also appropriate to say that both Two-Parameter Beta Method and Normal Approach Method are simpler versions of Pearson System Method; and yet the latter two methods have an advantage of using only the first two estimated conditional moments of τ, given $\hat{\tau}$, whereas the former requires the additional third and fourth conditional moments, whose estimations are less accurate compared with those of the first two conditional moments.

Our past experience with simulated data indicates that in many cases even by using the combination of relatively simplified approach and method we can estimate the operating characteristics fairly accurately. For this reason and because of the advantages described in the preceding paragraph, our choice of approach and method in the present study is the combination of the Simple Sum Procedure of the Conditional P.D.F. Approach and the Normal Approach Method.

Let θ be ability, or latent trait, which assumes any real number, and k_g be any discrete response category to item g. We assume that there is a set of test items measuring θ whose characteristics are known. This set of test items is called Old Test.

Let $I(\theta)$ denote the test information function of the Old Test of n such items. The transformation of θ to τ is made by

$$\tau = C_1^{-1} \int_{-\infty}^{\theta} [I(t)]^{1/2} \, dt + C_0 \quad , \tag{3.1}$$

where C_0 is an arbitrary constant for adjusting the origin of τ, and C_1 is an arbitrary constant which equals the square root of the test information function, $I^*(\tau)$, of τ, so that we can write

$$C_1 = [I^*(\tau)]^{1/2} \tag{3.2}$$

for all τ. This transformation will be simplified if we use a polynomial approximation to the square root of the test information function, $I(\theta)$, which is accomplished by using the method of moments. Thus (3.1) can be changed to the form

$$\begin{aligned} \tau &\doteq C_1^{-1} \sum_{k=0}^{m} \alpha_k (k+1)^{-1} \theta^{k+1} + C_0 \\ &= \sum_{k=0}^{m+1} \alpha_k^* \theta^k \quad , \end{aligned} \tag{3.3}$$

where α_k $(=0,1,\ldots,m)$ is the k-th coefficient of the polynomial of degree m approximating the square root of $I(\theta)$, and α_k^* is the new k-th coefficient which is given by

$$(3.4)\qquad \alpha_k^* \begin{cases} = C_0 & k = 0 \\ = (C_1 k)^{-1}\, \alpha_{k-1} & k = 1,2,\ldots,m+1 \end{cases} .$$

The first through fourth conditional moments of τ, given $\hat{\tau}_s$, can be obtained from the density function, $g^*(\hat{\tau})$, of $\hat{\tau}$ and the constant C_1 by the following four formulae.

$$(3.5)\qquad E(\tau|\hat{\tau}_s) = \hat{\tau}_s + C_1^{-2}\frac{d}{d\hat{\tau}_s}\log g^*(\hat{\tau}_s) .$$

$$(3.6)\qquad \mathrm{Var.}(\tau|\hat{\tau}_s) = C_1^{-2}[1 + C_1^{-2}\frac{d^2}{d\hat{\tau}_s^{\,2}}\log g^*(\hat{\tau}_s)] .$$

$$(3.7)\qquad E[\{\tau - E(\tau|\hat{\tau}_s)\}^3|\hat{\tau}_s] = C_1^{-6}[\frac{d^3}{d\hat{\tau}_s^{\,3}}\log g^*(\hat{\tau}_s)] .$$

$$(3.8)\qquad E[\{\tau - E(\tau|\hat{\tau}_s)\}^4|\hat{\tau}_s] = C_1^{-4}[3 + 6C_1^{-2}\{\frac{d^2}{d\hat{\tau}_s^{\,2}}\log g^*(\hat{\tau}_s) + 3C_1^{-4}\{\frac{d^2}{d\hat{\tau}_s^{\,2}}\log g^*(\hat{\tau}_s)\}^2 + C_1^{-4}\{\frac{d^4}{d\hat{\tau}_s^{\,4}}\log g^*(\hat{\tau}_s)\}] .$$

Note that in the above formulae the first moment is about the origin, while the other three are about the mean. The two coefficients, β_1 and β_2, and Pearson's criterion κ are obtained by

$$(3.9)\qquad \beta_1 = \mu_3^2\,\mu_2^{-3}$$

$$(3.10)\qquad \beta_2 = \mu_4\,\mu_2^{-2} ,$$

and

$$(3.11) \qquad \kappa = \beta_1(\beta_2+3)^2[4(2\beta_2-3\beta_1-6)(4\beta_2-3\beta_1)]^{-1} \quad ,$$

by substituting μ_2 , μ_3 and μ_4 by $\mathrm{Var.}(\tau|\hat{\tau}_s)$, $E[\{\tau-E(\tau|\hat{\tau}_s)\}^3|\hat{\tau}_s]$ and $E[\{\tau-E(\tau|\hat{\tau}_s)\}^4|\hat{\tau}_s]$, respectively, which are obtained by formulae (3.6), (3.7) and (3.8).

In the Simple Sum Procedure of the Conditional P.D.F. Approach, the operating characteristic, $P_{k_g}(\theta)$, of the discrete item response k_g of an "unknown" item g is estimated through the formula

$$(3.12) \qquad \hat{P}_{k_g}(\theta) = \hat{P}^{*}_{k_g}[\tau(\theta)] = \sum_{s\in k_g} \phi(\tau|\hat{\tau}_s)[\sum_{s=1}^{N} \phi(\tau|\hat{\tau}_s)]^{-1} \cdot$$

where s $(=1,2,\ldots,N)$ indicates an individual examinee, and $\phi(\tau|\hat{\tau}_s)$ denotes the conditional density of τ , given $\hat{\tau}_s$. This conditional density is estimated by using the estimated conditional moments of τ , given $\hat{\tau}_s$. In the Normal Approach Method, $\phi(\tau|\hat{\tau}_s)$ is approximated by the normal density function, using the first two estimated conditional moments of τ , given $\hat{\tau}_s$, which are given by (3.5) and (3.6), respectively, as its parameters.

IV. Old Test

In this study, we need some suitable substitute for the Old Test, since there is no set of test items measuring the same vocabulary ability whose characteristics are known. To handle this

situation, we use the Level 11 Vocabulary Subtest itself twice, i.e., first as the Old Test and later as the set of "unknown" test items.

On the first stage, each item is rescored as "right" or "wrong", i.e., dichotomously, and the normal ogive model on the dichotomous response level is assumed. We accept this model tentatively, and the item parameter estimation is made for each of the forty-three test items. On the second stage, these forty-three test items are treated as they are, i.e., as multiple-choice test items with polychotomous item responses. The "unknown" operating characteristic is to be estimated, therefore, for each of the four alternative answers of each item. As the result, we will obtain the estimated plausibility functions of the distractors for each item. In addition to this, the estimated operating characteristic of the correct answer of each item is compared with the hypothesized normal ogive function as a part of the model validation process, which will be introduced in Section 8. If the model is validated, then we will accept the estimated operating characteristics of the incorrect alternative answers as the estimated plausibility functions of the distractors. If not, we will examine the invalidated test items, and either assume more suitable models for them or discard them, to produce a new Old Test and repeat the estimation process all over again.

The item characteristic function, $P_g(\theta)$, of item g in the normal ogive model is given by

$$(4.1) \qquad P_g(\theta) = (2\pi)^{-1/2} \int_{-\infty}^{a_g(\theta - b_g)} e^{-\frac{u^2}{2}} du \ ,$$

where a_g is the item discrimination parameter and b_g is the item difficulty parameter.

V. Item Parameter Estimation for the Old Test Items Following the Normal Ogive Model

It is assumed that the response tendencies of our 2,364 examinees behind the forty-three items of the Level 11 Vocabulary Subtest have a multinormal distribution as their joint distribution. If there exists a single common factor behind these forty-three response tendencies, then we shall be able to operationally define the factor as the vocabulary ability for the contents of this specific subtest. As the result of this assumption, the ability distribution for these 2,364 subjects will also be normal, and we shall define the origin and the unit of the ability scale as the mean and the standard deviation of this normal distribution.

The tetrachoric correlation coefficient is obtained for each pair of test items, using the program written by the author. The resulting inter-item correlation matrix is given as Table 5-1. Those tetrachoric correlation coefficients were adjusted for the unbiasedness, which means that each value is a little less in the absolute value than the straightforward sample correlation coefficient. The item numbers in this table, which range from 24 to 66 , are the same as those used in the actual Iowa Vocabulary Test. We can see in this table that all the correlation coefficients are

TABLE 5-1

Tetrachoric Inter-Item Correlation Matrix for the Forty-Three Old Test Items.

non-negative, the fact which indicates the existence of a strong, dominating common factor. This inter-item correlation matrix, R , was subtracted by the covariance matrix of the unique factor matrix, V , and the resulting matrix was factor analyzed, using the computer program for principal factor solution in Biomedical Computer Programs Multivariate Analysis Series 4 (BMDP4M). Actually the matrix (R-V) was obtained by a usual iterative estimation of each of the n communalities, with the squared multiple correlation of each variable with all other variables as its initial estimate.

The same procedure was applied for each of the other ten Level 11 Subtests, and the resulting sets of eigenvalues are shown in Table 5-2*, except for those of the Level 11 Reading Comprehension Subtest (R)**. Inspection of this table tells us that Vocabulary

---

*The computer program is written in the way that we can adjust the accuracy of the estimation of correlation coefficients in certain ways. After one way was applied for all the subtests, it was redone for Vocabulary Subtest by increasing the accuracy for a certain range of correlation coefficients, and the new result was used in the present study. Although the discrepancies are small, in this sense the results of the other nine subtests are not exactly comparable to the result of the Vocabulary Subtest. Also, the numbers of common factors used for the reestimations of the communalities are much less for the other subtests than 40 which was used for the Vocabulary Subtest, i.e., 15 , 15 , 13 , 15 , 10 , 15 , 20 , 15 and 15 , respectively .

**For this specific subtest, we obtained the message that the matrix is not positive semi-definite. It is suspected that there are a substantial number of zeros in the correlation matrix because of the unbiasedness adjustment, and this may be one of the reasons for the message.

TABLE 5-2

Eigenvalues of the Matrix (R-V) for Each of the Ten Level 11 Subtests Obtained As the Results of the Principal Factor Solution of Factor Analysis.

Subtest is one of the few subtests whose second largest eigenvalue is substantially less than the first and also not so much greater than the third and other negligibly small eigenvalues, the fact which practically indicates a single common factor structure. This may be due to the fact that reading ability is always required in the performance in any subtest in addition to the content of measurement, but, unlike in the other nine subtests, in Vocabulary Subtest those two abilities are close in nature. In any case, this result is one of the reasons why Vocabulary Subtest was selected for the present study.

The factor loading matrix of the forty-three response tendencies is given as Table 5-3. We can see in this table that all the factor loadings on the first common factor are positive, and, except for those of items 24 and 44 , they are greater than 0.300 , ranging from 0.316 for item 39 to 0.691 for item 30 . The largest cluster of factor loadings we can find in those common factors excluding those in the first one is the pair in the fourth factor, i.e., 0.393 for item 33 and 0.368 for item 44 . Most of the factor loadings on those other common factors are less than 0.300 in absolute value, the fact which indicates their weak influences. From this result, a decision was made to proceed by defining operationally the first common factor as the vocabulary ability and to use the whole set of items in the Subtest as the Old Test.

The proportion correct, p_g , for each item g is given in Table 5-4. In the same table, also presented are the normal deviate, $\hat{\gamma}_g$, corresponding to the proportion correct p_g , and the estimated

item discrimination parameter, $\hat{a}_g$, and item difficulty parameter, $\hat{b}_g$, which are given by

(5.1) $$\hat{a}_g = \rho_g(1-\rho_g^2)^{-1/2}$$

and

(5.2) $$\hat{b}_g = \hat{\gamma}_g \rho_g^{-1} ,$$

where ρ_g is the factor loading of item g on the first common factor. Those values thus calculated will serve as the estimated item parameters in the normal ogive model on the dichotomous response level, whose item characteristic function is given by (4.1), for each Old Test item.

VI. Test Information Function of the Old Test and the Transformation of the Latent Trait θ to τ

The test information function, $I(\theta)$, of the Old Test is given by the sum total of the item information function, $I_g(\theta)$, which can be written as

(6.1) $$I_g(\theta) = [\frac{\partial}{\partial\theta} P_g(\theta)]^2 [P_g(\theta)Q_g(\theta)]^{-1} ,$$

where $P_g(\theta)$ is the item characteristic function given by (4.1) and

(6.2) $$Q_g(\theta) = 1 - P_g(\theta) .$$

Thus we can write

$$(6.3) \qquad I(\theta) = \sum_{g=1}^{n} I_g(\theta) \quad .$$

It has been pointed out (Samejima, RR-80-2, Final Report) that the square root of the test information function, rather than the test information function itself, is a useful function in many ways. Among others, it can be used in the process of transforming the original latent trait to another, which has a constant amount of test information for the range of ability of interest, as we have seen in Section 3.

Figure 6-1 presents the square root of the test information function of the Old Test by a solid line. We can see in this figure that our Old Test is most informative around $\theta = -0.4$, i.e., a little below the average ability level of our subjects. This is expected from the fact that thirty test items out of the total of forty-three have negative difficulty parameters, and twenty-eight test items have their difficulty parameters between -1.0 and 0.2, as is observed in Table 5-4. In the same figure, also presented by a dotted line is the polynomial of degree 7 obtained by the method of moments, using the interval of θ, $(-5.0, 5.0)$. The actual formula of this polynomial is given by

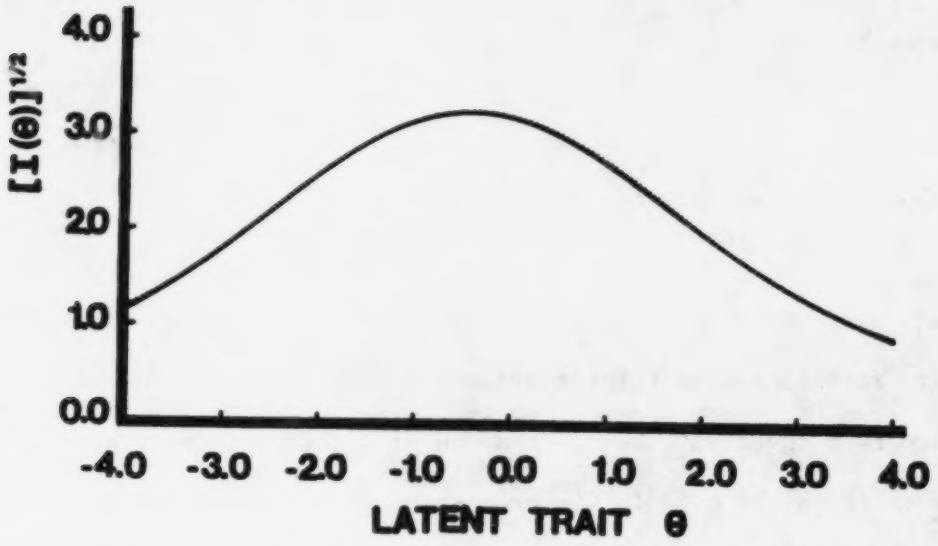

FIGURE 6-1

Square Root of Test Information Function $[I(\theta)]^{1/2}$ of the Level 11 Vocabulary Subtest (Solid Line) And Its Approximation by the Polynomial of Degree 7 Obtained by the Method of Moments with the Interval of θ, [-5.0, 5.0] (Dotted Line).

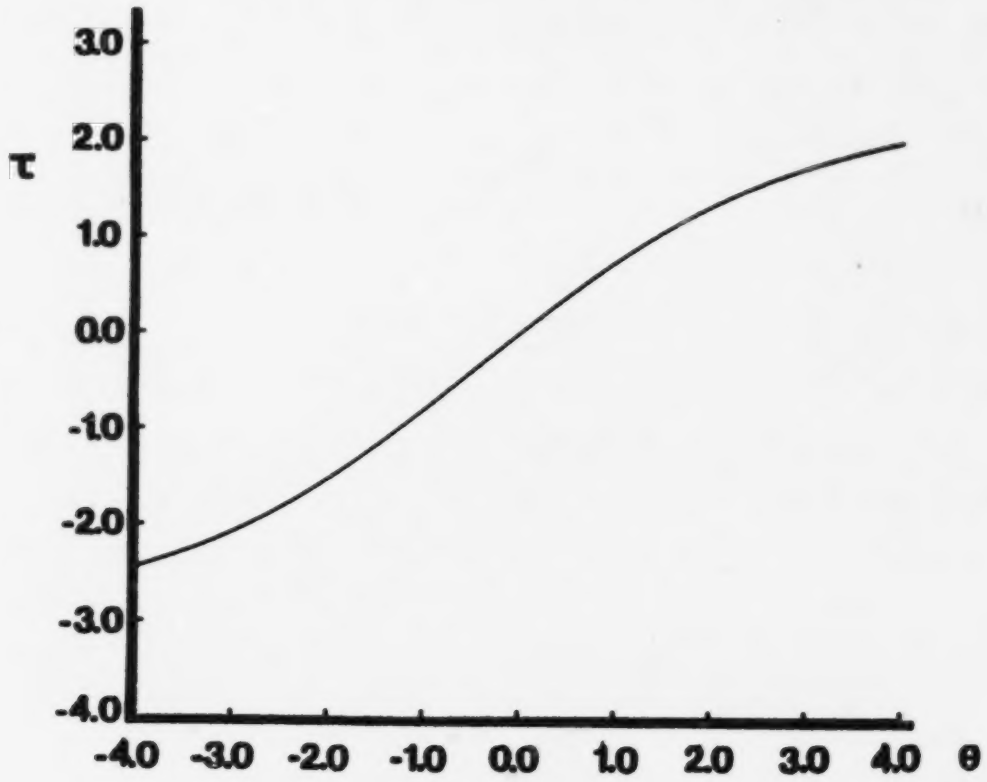

FIGURE 6-2

Polynomial Transformation of θ to τ.

$$(6.4) \qquad [I(\theta)]^{1/2} \doteq 3.1915950 - 0.23604972\theta - 0.27322550\theta^2 + 0.02624825\theta^3 + 0.01231557\theta^4 - 0.00114859\theta^5 - 0.00022787\theta^6 + 0.00001832\theta^7 \quad .$$

We can see in Figure 6-1 that this polynomial and the actual square root of the test information function are almost identical with each other for the interval of θ , $(-4.0, 4.0)$. This proves that the polynomial given by (6.4) makes a good substitute for the square root of the test information function, the result which is expected from the fact that the polynomial obtained by the method of moments is also the least squares solution for the specified degree of polynomial and interval of θ (Samejima and Livingston, RR-79-2). Actually, the method of moments was tried with four different intervals of θ , i.e., $(-4.0, 4.0)$, $(-4.5, 4.5)$, $(-5.0, 5.0)$ and $(-5.5, 5.5)$, and the above result showed the best fit. Those coefficients, σ_k $(k=0,1,2,\ldots,7)$, of the polynomials of degree 7 obtained by using the four different intervals of θ are shown in Appendix as Table A-1, together with the coefficients of the polynomials of degrees 3, 4, 5 and 6 obtained similarly by using those four intervals of θ , respectively. In this table, also presented are the original and revised coefficients, which mean those obtained by adjusting the area under the curve of $[I(\theta)]^{1/2}$ for the specified interval of θ to unity, with the midpoint of the interval and real origin of the scale as the origin, respectively. The revised coefficients were further modified to the "corrected" coefficients by readjusting the area

under the curve of $[I(\theta)]^{1/2}$ for the specified interval of θ to its real value.

The polynomial for transforming θ to τ was obtained by (3.3) and (3.4), using the coefficients, a_k $(k=0,1,2,\ldots,7)$, in (6.4) and setting the two constants, $C_0 = 0.0$ and $C_1 = 4.0$. The resulting polynomial of degree 8 is given by

$$\begin{aligned}(6.5)\quad \tau(\theta) = {} & 0.00000000 + 0.79789874\theta - 0.02950621\theta^2 - 0.02276879\theta^3 \\ & + 0.00164051\theta^4 + 0.00061577\theta^5 \\ & - 0.00004785\theta^6 - 0.00000813\theta^7 + 0.00000057\theta^8 .\end{aligned}$$

Figure 6-2 presents this polynomial of degree 8 for transforming θ to τ.

We can write for the square root of the test information function, $I^*(\tau)$, for the transformed latent trait τ

$$(6.6)\quad [I^*(\tau)]^{1/2} = [I(\theta)]^{1/2} \frac{d\theta}{d\tau} .$$

Figure 6-3 presents the square root of the test information function of τ thus obtained by using the approximated polynomial for $[I(\theta)]^{1/2}$ given by (6.4), and the derivative of τ obtainable from (6.5). Since the interval of θ, $(-4.0, 4.0)$, corresponds to the interval of τ, $(-2.44244, 2.02098)$, as we can see in Figure 6-2, the latter interval is shown by arrows in Figure 6-3. We can see that for this interval of τ the approximated square root of the test

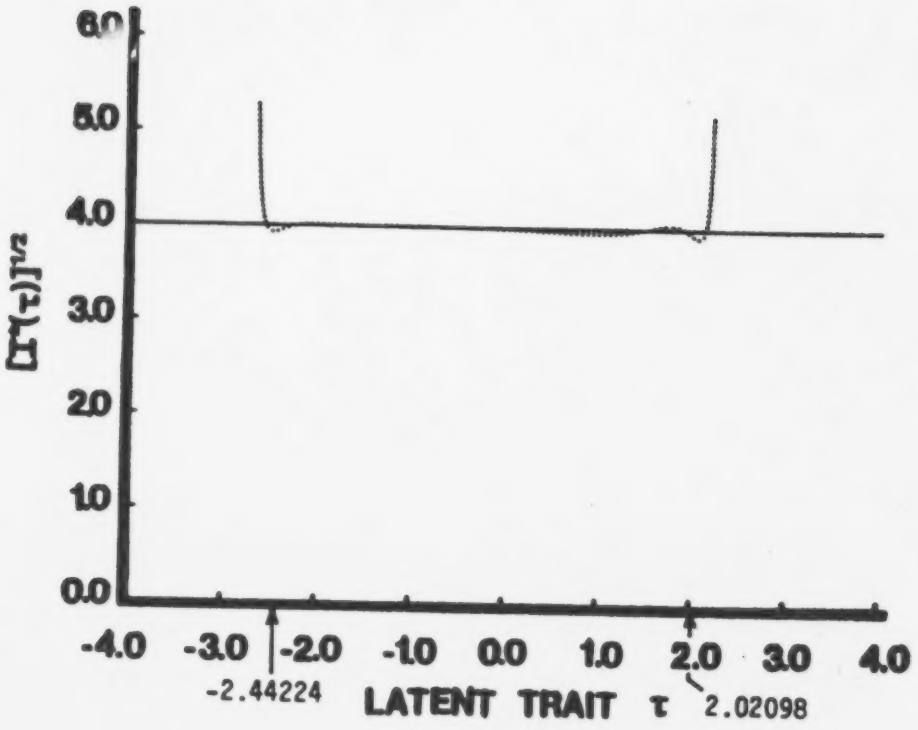

FIGURE 6-3

Square Root of Test Information Function $[I^*(\tau)]^{1/2}$ of the Level 11 Vocabulary Subtest Obtained from the Polynomial Transformation of θ to τ (Dotted Line) And Its Target (Solid Line).

information function, $[I(\tau)]^{1/2}$, is almost constant, i.e., very close to 4.0 .

The maximum likelihood estimate of θ was obtained for each individual subject from his response pattern on the Old Test items. Let $\hat{\theta}_s$ denote this maximum likelihood estimate of ability θ for subject s . This maximum likelihood estimate, $\hat{\theta}_s$, can directly be transformed to the maximum likelihood estimate of the transformed ability τ, which is denoted by $\hat{\tau}_s$, through (6.5). This was done for the 2,356 subjects, whose $\hat{\theta}_s$'s are within the interval, $(-3.75, 3.75)$. On this stage, eight subjects were excluded from our data, since three of them obtained positive infinity for $\hat{\theta}_s$, three obtained 5.94848 , 4.92496 and 4.37878 , respectively, and two obtained 3.89343 . They were excluded permanently from the rest of the research.

Figure 6-4 presents the frequency distribution of the 2,356 $\hat{\tau}_s$, with the interval width of 0.25 . In the same figure, also presented by dotted and dashed lines are the polynomials of degree 3 and 4, respectively, which were obtained by the method of moments. In these two cases, the interval of $\hat{\tau}$ is $(-1.91742, 1.95366)$, taking the lowest and the highest values of $\hat{\tau}_s$ among the 2,356 as its two endpoints. These two polynomials of degrees 3 and 4 are given by

$$\hat{g}^*(\hat{\tau}) = 0.42358084 - 0.046813019\hat{\tau} - 0.13270786\hat{\tau}^2 + 0.020014202\hat{\tau}^3 \tag{6.7}$$

and

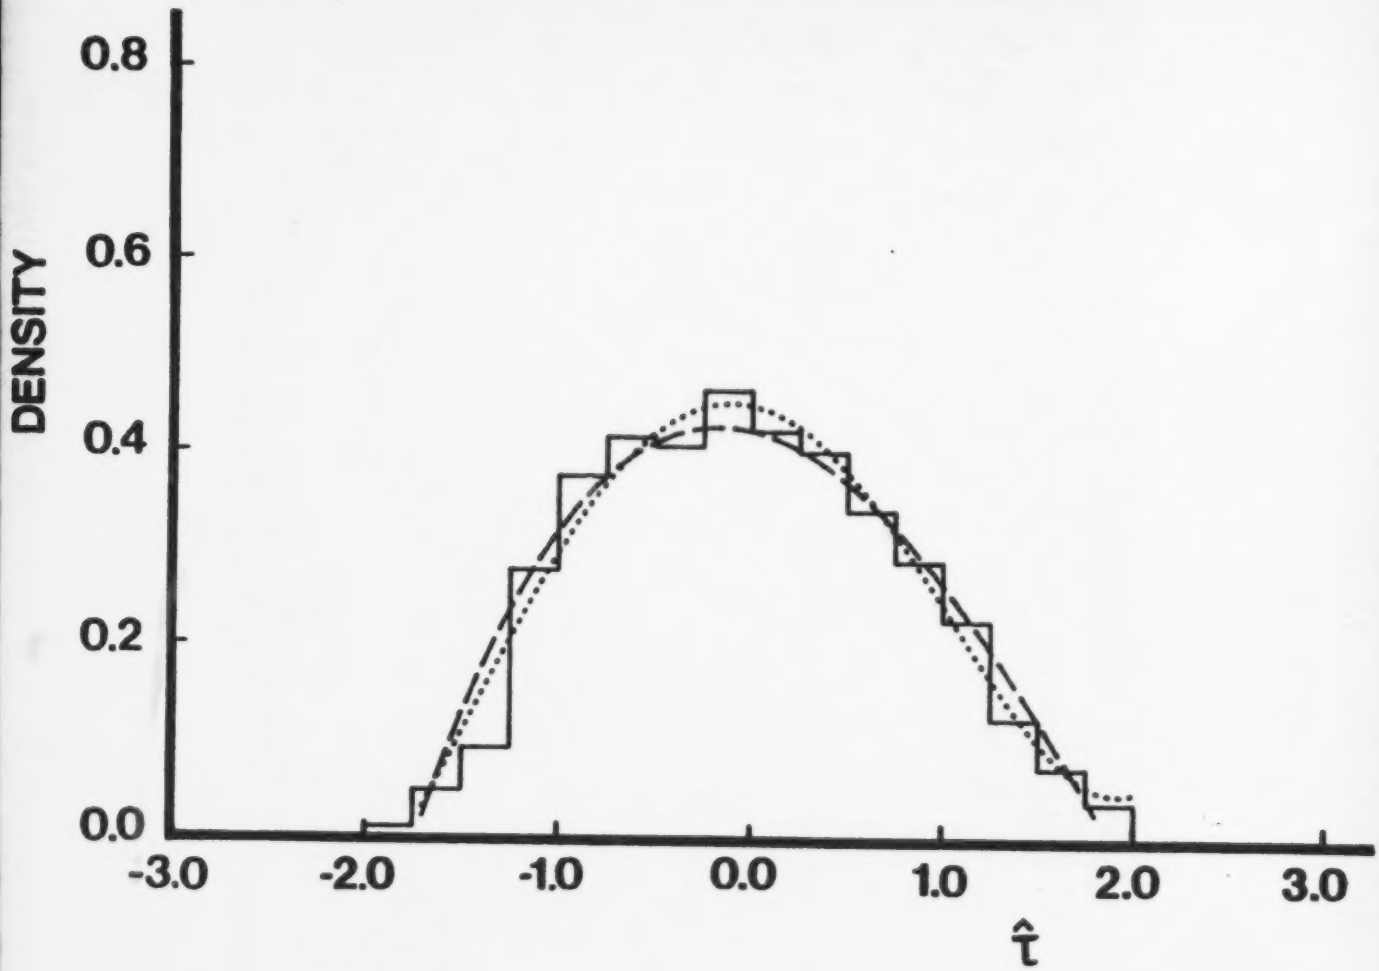

FIGURE 6-4

Frequency Distribution of the 2,356 $\hat{\tau}_s$ Based upon the Old Test (Histogram), And the Two Polynomials of Degree 3 (Dashed Line) And of Degree 4 (Dotted Line) Obtained by the Method of Moments.

and

$$(6.8) \qquad \hat{g}^*(\hat{\tau}) = 0.45023559 - 0.044232853\hat{\tau} - 0.20387563\hat{\tau}^2 + 0.018406862\hat{\tau}^3 + 0.022176405\hat{\tau}^4 \ ,$$

respectively. We can see in Figure 6-4 that these two polynomials fit the frequency distribution very well. Hereafter, we shall call the situations in which (6.7) and (6.8) are adopted as the estimated density function, $\hat{g}^*(\hat{\tau})$, Degree 3 Case and Degree 4 Case, respectively.

VII. Estimated Plausibility Functions of the Distractors

Using the polynomials introduced in the preceeding section as the estimated density, $\hat{g}^*(\hat{\tau})$, the first through fourth conditional moments of τ , given $\hat{\tau}_s$, were obtained for each individual $\hat{\tau}_s$, by the formulae (3.5) through (3.8). From those results, the two coefficients β_1 and β_2 and Pearson's criterion κ were also computed by formulae (3.9), (3.10) and (3.11) . They are all presented in Appendix as Tables A-2 and A-3 for Degree 3 and 4 Cases, respectively.

Table 7-1 presents the frequency distribution of the 2,356 $\hat{\tau}_s$'s with respect to the types of the conditional distribution of τ , given $\hat{\tau}_s$, in both Degree 3 and 4 Cases. These types, 1 through 7, are Pearson's Types (Elderton and Johnson, 1969; Johnson and Kotz, 1970) assigned by evaluating the values of the criterion κ . We can see in this table that in both Degree 3 and 4 Cases more than sixty

TABLE 7-1

Frequency Distribution of the 2,356 $\hat{\tau}_s$ with Respect to Their Pearson Types for the Conditional Distributions of τ .

Total	2,356	2,356

und. 1 : Undefined Due to Negative Even Conditional Moment(s).

und. 2 : Undefined Due to Negative P.D.F.

percent of the cases belong to the normal distribution, while most of the others belong to the Beta distribution, i.e., either Pearson's Type 1 or 2. There are some cases whose conditional distributions of τ are undefined, either due to negative estimated even conditional moments or to negative estimated conditional probability densities. Those subjects have to be excluded from the rest of the research.

The above result justifies our choice of Normal Approach Method in both Degree 3 and 4 Cases. A close examination of Tables A-2 and A-3 in Appendix further discloses the fact that, in most cases where the conditional distributions of τ belong to other types of Pearson's distributions than normality the values of β_2 are very close to 3.000 , the number which characterizes the normal distribution.

Since these two sets of results are very similar to each other, hereafter we deal solely with Degree 4 Case. It is worth noting, however, that the results of Degree 3 Case would be just as respectable as those of Degree 4 Case, in spite of the fact that the degree of the polynomial approximating $g^*(\tau)$ is one less and as small as 3 . A slight disadvantage of Degree 3 Case appears in the number of subjects to be discarded because of the result shown in Table 7-1, i.e., 127 compared with 53 in Degree 4 Case.

Before proceeding further, we notice that a simple, straightforward estimation of the plausibility functions of the distractors can be made by taking the frequency ratios of the subgroups of examinees who selected the separate alternative answers,

which are calculated for some appropriately set subintervals of $\hat{\theta}$. This was done by using thirty subintervals of $\hat{\theta}$ with unequal widths to make the total numbers of subjects in the separate subintervals of approximately equal, i.e., 78 or 79 . The results are shown in Appendix as Figure A-1, together with the item characteristic functions in the normal ogive model, whose discrimination and difficulty parameters are shown in Table 5-4 as $\hat{a}_g$ and $\hat{b}_g$. In those graphs, the frequency ratios of the correct answers, A ,are represented by dots, and those of the distractors, B , C and D , are represented by dashes of three increasing lengths.* We can see from those graphs that the set of frequency ratios for the correct answer matches the corresponding normal ogive curve well in most cases.

The operating characteristics of the four alternative answers were obtained for each of the forty-three vocabulary test items using the Simple Sum Procedure of the Conditional P.D.F. Approach combined with the Normal Approach Method, which were introduced in Section 3.

---

* Because of the confidentiality of the Tests, we need to disguise the correct answer for each item from the reader. For this reason, the alternative answers, 1 , 2 , 3 and 4 , were randomized, so that we shall always call the correct answer the alternative A , and the three incorrect answers B , C and D , throughout the rest of the present paper.

The resultant estimated operating characteristics are shown in Figure 7-1 by dotted and dashed lines, together with the normal ogive curve specified by the two estimated item parameters shown in Table 5-4, which is drawn by a solid line.

These results provide us with a variety of information. First of all, most of the nonparametrically estimated item characteristic functions are very close to the corresponding normal ogive curves, which are parametrically estimated item characteristic functions following the normal ogive model. Exceptions are the one for item 44 and, to a lesser extent, those for items 39 and 49 . Secondly, most of the sets of estimated plausibility functions of distractors indicate that they belong to the Informative Distractor Model rather than the Equivalent Distractor Model, which means each separate distractor provides us with its own information. The closest configuration of the estimated plausibility functions to the Equivalent Distractor Model may be the one for item 63 . There are pairs of distractors which show almost identical estimated plausibility functions with each other in certain items, however. We can see them in the alternatives B and C of item 24 , B and C of item 29 , C and D of item 30 , B and D of item 49 , B and C of item 50 , C and D of item 52 , B and C of item 53 , B and D of item 60 , C and D of item 61 and C and D of item 64 . Thirdly, there are certain distractors which attract the examinees strongly for certain specific ranges of ability. Table 7-2 presents those distractors under the label, "informative" .

Note that the distractors listed in Table 7-2 are only those which proved to be informative from the results of the present study, in which the estimated operating characteristics are truncated on the lower levels of ability. There is no way of knowing about the information provided by distractors on the levels of ability lower than -1.6, and it is suspected that there are many more informative distractors than those which the present results have disclosed. We shall be able to discover them by analyzing data collected upon a group of younger subjects in future research. Fourthly, we notice that there are some distractors which show unusually flat plausibility functions. They are listed in Table 7-2 under the label, "flat". Somehow those distractors attract high levels of subjects almost equally as they do lower levels of subjects. It will be worthwhile to use this information and go back to the items having such distractors to find out if the alternative answers selected for those items are suitable, or if the question itself is well addressed.

In any case, the above information provides us with valuable resources of item analysis. Effort can be focused upon the improvement of each item using this information, until we find a more informative set of alternatives.

We can see in Figure 7-1 that for some items the implicit orders of the distractors have been disclosed by the present research. For example, in item 46, the alternative C appears to be the second best answer, although the order between the alternatives B and D is not obvious. It may be appropriate to give the graded scores, 0,

1 and 2 , to the combination of B and D , to the alternative C and to the alternative A , respectively, for this item. Thus the three functions, which represent the cumulative operating characteristics assigned to x_{46} (=0,1,2) or greater, were obtained from the result of Figure 7-1 and those graded scores, and are shown in Figure A-2 in Appendix. Similar functions were also obtained for sixteen other items and are shown in the same figure. In those seventeen graphs we can see that for items which were presented later in the subtest the operating characteristics for $x_g \geqslant 0$ decrease as θ decreases, disclosing a strictly decreasing operating characteristic for the "no answer" category.

Because of the confidentiality of the test, here we will not discuss the contents of the alternatives which proved to be informative, or which provide us with unusual configurations of the estimated operating characteristics, and so forth. It might be added, however, that in many cases we can find possible reasons for those characteristics of the estimated plausibility functions, although in some other cases we are rather puzzled.

VIII. Model Validation

We have seen in the results of previous sections that there is enough evidence to support the set of assumptions we adopted in the present research. First of all, the normal ogive model assumed for the Old Test items is well supported by the goodness of fit of the item characteristic functions estimated by assuming the normal ogive

model to those estimated by our combination of nonparametric method and approach. This result supports not only the assumed normal ogive model but also the multivariate normality assumed for the forty-three response tendencies.

It may be more appropriate to repeat the whole procedure after excluding such items as items 44 , 39 and 49 from the Old Test, which do not show very good fits of the normal ogive functions. Considering the fact that there are only a few items of poor fits, however, we cannot expect the repetition of the procedure with the new reduced Old Test to provide us with a substantially different set of results. The decision was made, therefore, against it.

Secondly, the use of the Normal Approach Method is well supported by the estimated conditional moments of τ , given $\hat{\tau}_s$, which are shown in Appendix as Tables A-2 and A-3 and summarized in Table 7-1 in the preceding section.

In order to proceed further in model validation, the following procedure was added. For each pair of items, using their estimated normal deviates, $\hat{\gamma}_g$, which are presented in Table 5-4, and the estimated tetrachoric correlation coefficient between their response tendencies, the two-by-two contingency table is produced from the bivariate normal distribution. The chi-square statistic of the four frequencies in the actual contingency table was computed by using the frequencies in the contingency table thus produced as the "theoretical" values. Since the empirically obtained normal deviates and tetrachoric correlation coefficient are used in obtaining

the "theoretical" frequencies, the resultant statistic should have a negligibly small value, in order for the bivariate normal assumption to be validated.

As it turned out, most of the chi-square values are very small. Table 8-1 presents two such examples, i.e., those chi-square statistics for items 62 and 30 , against each of the other respective forty-two items. In the same table, also presented are two more examples whose chi-square values are largest, i.e., those for items 24 and 44 . In fact, item 44 has unusually large chi-square statistics in its row, as is obvious in this table. It is interesting to note that this item is the one which provides us with the poorest fit of the normal ogive curve to the nonparametrically estimated item characteristic function, as we have seen in Figure 7-1. In contrast to this, item 24 provides us with a surprisingly good fit, as is also seen in Figure 7-1. It is worth noting that these two items are the items whose estimated difficulty parameters are by far the largest in absolute value (cf. Table 5-4). Similar results for the other items are given in Appendix as Table A-4. In this table, all the chi-square statistics greater than, or equal to, 0.1 are circled. We can see that many items have small chi-square values against other items, except for those against items 44 and 24 .

In order to investigate the relationship between the chi-square value and the goodness of fit of the normal ogive curve to the nonparametrically estimated item characteristic function, all the forty-three Old Test items are categorized into four classes, i.e.,

TABLE 8-1

Four Examples of the Sets of Chi-Square Statistics, Showing Good Fits (Items 62 And 30) And Bad Fits (Items 24 And 44) to the Bivariate Normality.

good, fairly good, fairly poor and poor, with respect to the goodness of fit inspected by the eye in Figure 7-1. Table 8-2 presents the item numbers thus categorized with respect to the goodness of fit and the frequencies of chi-square values greater than, or equal to, 0.1 . We can see in this table that there is a negative correlation between the goodness of fit and the frequency of chi-square values which are greater than, or equal to, 0.1 , the result which is logically expected. On the other hand, it is worth noting that there are a substantial number of items which have high frequencies of large chi-square statistics, and yet showing good fits of the normal ogive functions. This appears to indicate the robustness of the whole procedure used in the present research.

We notice from Table A-4 that most circles will disappear if we exclude those items which have thirteen or more circles in their rows. In fact, there are some which will not have any circles in their rows at all if we solely exclude items 44 and 24 . For convenience, such items are categorized as Group A. If we further exclude those items having 19 to 21 circles in their rows, i.e., items 39 , 50 , 57 , 33 and 37 , then there will be more items which do not have any circles in their rows at all. This second group is called Group B. Similarly, Group C consists of the items which will not have any circles in their rows if we further exclude the items having 13 to 16 circles in their rows, i.e., items 53 , 35 , 42 , 49 and 58 . The rest of the items are categorized as Group D. Table 8-3 presents the item numbers of the thirty-one items classified

Item Numbers of the Thirty-One Items Categorized with Respect to the Groups They Belong to, and Also to the Goodness of Fit of the Normal Ogive Curves to the Estimated Operating Characteristic of the Correct Answer Obtained By the Simple Sum Procedure of the Conditional P.D.F. Approach Combined with the Normal Approach Method.

Group	Good	Fairly Good
A	29, 30, 31, 45, 62, 64	48
B	25, 36, 46, 55, 66	60
C	26, 28, 32, 38, 43	40, 41, 51, 52, 54, 59, 61, 63, 65
D	34, 47	27, 56
Total Number	18	13

with respect to the above categorization and the goodness of fit. There is a substantial difference between the goodness of fit of Group C and those of Groups A and B, as is expected.

We can say that the results of this additional process further support our whole procedure used in the present research.

IX. Discussion and Conclusions

A set of data based upon the Level 11 Vocabulary Subtest of the Iowa Tests of Basic Skills was analyzed, using the Simple Sum Procedure of the Conditional P.D.F. Approach combined with the Normal Approach Method, and the plausibility functions of the distractors of these items were estimated. In so doing, the same set of test items was used twice, i.e., once as the dichotomized Old Test items and then as the polychotomous test items whose characteristics are to be discovered. The results proved that most of the test items are not likely to follow the Equivalent Distractor Model, to which the three-parameter logistic or normal ogive model belongs. In fact, we have discovered many distractors which are informative, and the results suggest that most of these items follow the Informative Distractor Model. Model validation was performed from several different angles, and positive results were obtained.

Methodologies involved in the present study appear to be promising, and they will find their usefulness in many other future studies. It is the author's belief that more test data should be analyzed with the kind of rigorousness involved in the present study.

Since the results indicate that these test items belong to the Informative Distractor Model, the next logical step will be to find out how we can make the best use of the information obtainable from the distractors as well as from the correct answers, in order to increase the efficiency of ability estimation.
